MAX30210

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

General Description

The MAX30210 operates from 1.7V to 2.0V supply voltage, and is a low-power, high-accuracy digital temperature sensor with $\pm 0.1^{\circ}$ C accuracy from $+20^{\circ}$ C to $+50^{\circ}$ C and $\pm 0.15^{\circ}$ C accuracy from -20° C to $+85^{\circ}$ C. The MAX30210 has a 16-bit resolution (0.005°C).

The device uses a standard I²C serial interface to communicate with a host controller. There are four functional I/Os. Those functions include a dedicated interrupt pin, a shared external convert and power-down functional pin, and two target address select pins.

The MAX30210 includes a 64-word FIFO for the temperature data and also includes high and low threshold digital temperature alarms along with FIFO full alert. The device is available in a 0.968mm x 0.968mm x 0.5mm, 9-pin WLP package.

Applications

- Wearable Devices for Fitness, Wellness, and Medical Applications
- Medical Thermometers
- Hearing Aids
- Smart Clothing

Benefits and Features

- High Accuracy and Precision
 - ±0.1°C Accuracy from +20°C to +50°C
 - ±0.15°C Accuracy from -20°C to +85°C
- Low-Power Consumption
 - 1.7V to 2.0V Operating Voltage
 - 61µA Operating Current during Measurement
 - 0.75µA Standby Current
 - 10nA Power-Down Current
 - 8ms Integration Time
- Safety and Compliance
 - High and Low Temperature Alarms
- Digital Interface
 - Shared External Convert Temperature and Power-Down Input Pin
 - Dedicated Interrupt Output Pin
 - Autonomous Conversion Mode
 - 16 Different I²C Target Address Options
 - 48-Bit Unique ROM IDs Allow Device to be NIST Traceable

Ordering Information appears at end of data sheet.

Absolute Maximum Ratings

V _{DD} to GND	0.3V to +2.2V	Storage Temperature Range	55°C to +150°C
SDA, SCL, A0, A1, CVT/PDB, INT to GND	0.3V to +6.0V	Lead Temperature (soldering, 10s)	+260°C
Operating Temperature Range	40°C to +85°C	Soldering Temperature (reflow)	+260°C
Junction Temperature	+150°C		

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Information

9-Pin WLP

Package Code	N90A0+1			
Outline Number	<u>21-100600</u>			
Land Pattern Number	Refer to the Application Note 1891: Wafer-Level Packaging (WLP) and Its Applications.			
THERMAL RESISTANCE, FOUR-LAYER BOARD				
Junction-to-Ambient (0 _{JA})	94°C/W			

For the latest package outline information and land patterns (footprints), go to <u>www.maximintegrated.com/packages</u>. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to <u>www.maximintegrated.com/</u> <u>thermal-tutorial</u>.

Functional Diagrams

Diagram 1

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Detailed Description

The MAX30210 temperature sensor measures temperature with ±0.1°C accuracy over a +20°C to +50°C temperature range and ±0.15°C accuracy over a -20°C to +85°C temperature range. The device communicates over a standard I²C interface with serial data (SDA) and serial clock (SCL) lines to read the FIFO, which contains up to 64, 2-byte temperature readings from a 16-bit ADC measurement. The device operates properly over a -40°C to +85°C temperature range without any damage. There are multiple ways to take a temperature measurement including single-shot mode. autonomous conversion mode, and using an external trigger through the CVT/PDB pin. In the autonomous conversion mode, the MAX30210 performs temperature conversions based on a programmable rate and stores the temperature result into the FIFO at the end of every active conversion. Once the data fills up the FIFO, the memory-mapped register contains a FIFO full alarm to be able to save all the data collected. The memory-mapped registers contain programmable high-alarm and low-alarm trigger registers as well. The Alarm High, Alarm Low, and Setup registers are volatile, and do not retain data when the device is powered down. The MAX30210 has four additional pins where three are of fixed function and the fourth is a shared functional pin. Two of the pins (A0, A1) are dedicated for the I²C target address which can be tied to V_{DD} , SCL, SDA, and GND and provide up to 16 different I²C target address options. The final two pins are for interrupt (INT) and convert/power-down (CVT/PDB). The interrupt (INT) pin wakes up the microcontroller unit (MCU) during a qualified event and the convert/power-down (CVT/PDB) pin allows for either an external source to toggle the pin to start a conversion or power-down the part.

Measuring Temperature

The device powers up in a low-power standby state. There are three different ways to initiate a temperature measurement:

- Controller writes a '1' to CONVERT_T[0](0x2A) register.
- Falling/Rising edge trigger on CVT/PDB pin input (EXT_CVT_EN[7](0x12) = 1).
- Turn on autonomous conversion mode after setting up the registers.

In any of these methods, sampling should not exceed 20Hz to limit possible self-heating. Following the conversion, which takes 8ms (typ), the resulting temperature data is stored in the FIFO and the device returns to the standby state. CONVERT T automatically clears to '0' after the measurement is taken.

The output temperature data is calibrated in degrees Celsius. The temperature data is stored as a left-justified, 16-bit sign-extended two's complement number in the FIFO Data register (see <u>Table 1</u>). The data is two's complement where the most significant bit (MSB) determines the sign of the temperature with an MSB of 1 indicating a negative temperature and an MSB of 0 indicating a positive temperature.

To calculate the temperature from the measurement result, convert the two's complement value to the decimal value and use the following equation.

 $T = Decimal Value \times 0.005$

For example, if the result is 0x1CE8, convert to decimal to get 7400, then T = 7400 × 0.005 or 37°C. <u>Table 1</u> gives examples of digital output data and the corresponding temperature reading.

TEMPERATURE (°C)	DIGITAL OUTPUT (Binary)	DIGITAL OUTPUT (Hexadecimal)	DIGITAL OUTPUT (Decimal)
+70	0011 0110 1011 0000	36B0	14000
+50	0010 0111 0001 0000	2710	10000

Table 1. FIFO Data Format (continued)

External Convert Pin/Power-Down Input

The MAX30210 features a pin that is used for both an external conversion input (CVT) and powering down (PDB) the part to reduce current in between temperature conversions. The CVT input offers the ability to trigger a conversion by either a rising or falling edge. There are more details of the timing in the <u>Start-Up Timing</u> section in Figure 9 and Figure 10. To enable the CVT feature, set EXT_CVT_EN[7](0x12) = 1 and set the EXT_CVT_ICFG[6](0x12) bit to set the input active edge. The settings for both the CVT and the PDB features are listed in <u>Table 2</u>. Note, when PDB is brought high from Power Down to Power Up, all register contents restore to the power on reset values.

Table 2. CVT/PDB Pin Function

EXT_CVT_EN	EXT_CVT_ICFG	CVT/PDB	FUNCTION
0	X	GND	Power Down
0	Х	V _{DD}	Power Up
1	0	Pulse	Power Up, CVT On, Falling Edge Conversion
1	1	Pulse	Power Up, CVT On, Rising Edge Conversion

Autonomous Conversion Mode

When the AUTO[1](0x2A) is set to 1, the MAX30210 operates in autonomous conversion mode. The MAX30210 continuously performs temperature conversions in this mode based on the TEMP_PERIOD[3:0](0x29) settings and the resulting temperature measurement data is stored in the FIFO at the end of every active conversion. Every conversion cycle consists of an active conversion followed by a standby period. The device typically consumes 61µA during active conversion and 750nA in standby mode. Table 3 shares the corresponding bit settings and the sample rate.

Figure 1. Conversion Sample Period

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

TEMP_PERIOD	SAMPLE RATE (Hz)	SAMPLE PERIOD (sec)
0x0	0.015625	64
0x1	0.03125	32

0x7	2	0.5
0x8	4	0.25
0x9 to 0xF	8	0.125

Table 3. Temperature Sample Rate

MCU Interrupt Modes

High/Low Alarm

After the device performs a temperature conversion, the temperature value is compared with the user-defined two's complement alarm trigger values stored in the 2-byte ALARM_HI[15:0](0x22, 0x23) and 2-byte ALARM_LO[15:0](0x24,0x25) registers (see Figure 2). The default value for ALARM_HI is 0x7FFF (+163.835°C) and the default value for ALARM_LO is 0x8000 (-163.840°C). The MSB indicates if the value is positive or negative; for positive numbers the MSB is 0 and for negative numbers the MSB is 1. If the measured temperature is lower than ALARM_LO or higher than ALARM_HI, an alarm condition exists and corresponding status bit, TEMP_LO[3](0x00) or TEMP_HI[2](0x00) is set in the Status register. When the alarm condition is detected and the corresponding interrupt enable bit, TEMP_LO_EN[3](0x02) or TEMP_HI_EN[2](0x02) is set in the Interrupt Enable register and a hardware interrupt asserts on the INT pin, then the status bits, the alarm flag, and the hardware interrupt stay asserted until the Status register is read using the serial interface. The alarm flag only clears when STATUS is read. If the alarm flag is set and the next result does not trip the flag, then the flag remains set.

If the alarm settings change while the device is under an alarm condition, the alarm status must be cleared and another temperature conversion executed to update the alarm condition.

Figure 2. High/Low Alarm Threshold Register Format

Interrupt Mode

When the alert mode bit is set to 0 and autonomous conversion mode is enabled, the MAX30210 is set for interrupt mode alerts. In this mode, the MAX30210 sends an interrupt to the MCU when the temperature passes either the high temperature threshold or the low temperature threshold value. The alerts are cleared once the I^2C read occurs. Figure 3 shows how the mode works.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Figure 3. Interrupt Mode Timing Diagram

Comparator Mode

When the alert mode bit is set to 1 and autonomous conversion mode is enabled, the MAX30210 is set for comparator mode alerts. In this mode, the MAX30210 sends an interrupt to the MCU when the temperature is measured higher than the high temperature threshold. Both the high alert register and the interrupt pin stay asserted until the temperature falls below the set low temperature threshold value. The low alert flag is disabled and always read 0 in this mode. No alerts are cleared once the I²C read occurs. Figure 4 shows how the mode works.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Figure 4. Comparator Mode Timing Diagram

Rate-of-Change Alarm

An on-chip filter, when enabled, measures the slope of the previous N samples, is available after N samples have been collected and then updated for each additional sample. In the following example, N is set to 5. If the slope exceeds the setting in TEMP_INC_THRESH[7:0](0x26), an interrupt is asserted. Likewise, if the slope is less than the setting in TEMP_DEC_THRESH[7:0](0x27), an interrupt is set. Figure 5 shows measured data with eight sequential slope measurements.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Figure 5. Rate-of-Change Filter Applied to Temperature Measurements

When autonomous mode is enabled (AUTO[1](0x2A) = 1) and CHG_DET_EN[3](0x28) is set to 1, the MAX30210 enables a rate-of-change mode. The mode is also enabled when CHG_DET_EN is set to 1 and EXT_CVT_EN[7](0x12) is set to 1. <u>Table 4</u> summarizes how the mode is set.

Table 4. Rate-of-Change Alarm Mode

AUTO	EXT_CVT_EN	CHG_DET_EN	RATE OF CHANGE MODE
0	0	X	Disabled
Х	1	0	Disabled
1	0	0	Disabled
Х	1	1	Enabled
1	0	1	Enabled

When the rate-of-change mode is enabled, the MAX30210 provides a slope value based on a set number of temperature measurement samples (m°C/Sample) and stores the 2's compliment value in the TEMP_SLOPE[8:0](0x2D, 0x2E) registers. This value is compared to a user settable slope increase threshold TEMP_INC_THRESH[7:0](0x26) and the slope decrease threshold TEMP_DEC_THRESH[7:0](0x27). If the slope value is higher than the value in the TEMP_INC_THRESH, the TEMP_INC_FAST[4](0x00) bit is asserted. Likewise, if the slope value is lower than the value in the TEMP_DEC_THRESH, the TEMP_DEC_FAST[5](0x00) bit is asserted in the status register. There are interrupt options to send an interrupt to the INT pin if either the TEMP_DEC_FAST or the TEMP_INC_FAST bit is asserted by setting 1 to the TEMP_DEC_FAST_EN[5](0x02) or TEMP_INC_FAST_EN[4](0x02) bit, independently. One could choose to interrupt only on an increase slope threshold, a decrease slope threshold or choose to be interrupted by both. All interrupts and status bits are cleared upon I²C read.

These settings are dependent on the filter set in the RATE_CHG_FILTER[2:0](0x28) register. This register sets the length of the change in temperature FIR filter. The slope value is calculated based on the number of samples selected in this register and is stored in the TEMP_SLOPE registers as described above. No slope value is stored until the number of samples in the RATE_CHG_FILTER register has been taken. The user needs to set the appropriate number of samples to fit the application needs.

0x6	65
0x7	65

The TEMP_INC_THRESH setting is based on a positive slope in units of $5m^{\circ}C^{*}N/SAMPLE(S)$ where N = (0 to 255). Likewise, the TEMP_DEC_FAST_THRESH setting is based on a negative slope in units of $5m^{\circ}C^{*}N/SAMPLE(S)$ where N = (0 to 255).

Table 6. Change in Temperature Threshold Settings

VALUE	CHANGE IN TEMPERATURE/SAMPLE (m°C/SAMPLE)
0x0	0
0x1	5
0x2	10
0x3	15
0x4	20
0xFF	N*5 where N={0 to 255}

To set the expected threshold, the slope needs to be set based on the configured sample rate. Here are some examples sharing how the calculation is completed.

Table 7. Rate of Change Alarm Examples

SAMPLE RATE (SPS)	TEMPERATURE SAMPLES	CHANGE IN TEMPERATURE/ SAMPLE (m°C/sample)	CHANGE IN TEMPERATURE (m°C)	TIME PERIOD (SEC)	DESCRIPTION
8	9 [0x3]	5	5*(9-1) = 40	(9-1)/8 = 1	40m°C slope increase threshold over a 1-second time period.
8	65 [0x6, 0x7]	5	5*(65-1) = 320	(65-1)/8 = 8	320m°C increase over an 8-second time period
1	5 [0x2]	50	50*(5-1) = 200	(5-1)/1 = 4	200m°C slope increase threshold over a 4-second time period
1	17 [0x4]	50	50*(17-1) = 800	(17-1)/1 = 16	800m°C increase over a 16-second time period
0.0625	3 [0x1]	200	200*(3-1) = 400	(3-1)/0.0625 = 32	400m°C slope increase threshold over a 48-second time period
0.0625	9[0x3]	200	200*(9-1) = 1600	(9-1)/0.0625 = 128	1600m°C slope increase threshold over a 128-second time period

Start-Up Timing

The start-up timing and delays for the MAX30210 are shown in the waveform below. Figure 6 shows the typical time taken for the MAX30210 to wake up and be ready for I^2C communication.

Figure 6. Power-Up Timing

Figure 7 shows the typical start-up delay when the MAX30210 is used in autonomous mode.

Figure 7. Autonomous Conversion Mode

Figure 8 shows the typical start-up delay when the MAX30210 is used in single-shot mode initiated through I²C.

Figure 9 shows the typical start-up delay when the MAX30210 is used in single-shot mode initiated through the CVT pin.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Figure 9. Single-Shot Conversion Mode - through CVT

When using the CVT pin to initiate a conversion the pulse width of the CVT pin must meet the minimum requirements shown in <u>Figure 10</u>.

Figure 10. CVT Pulse Width Timing

FIFO Description

FIFO Data Format

The FIFO is 64 samples deep and is designed for 16-bit temperature data. The controller does a burst read of three bytes starting at register 0x08 to read one 16-bit temperature sample, referred to as a word, from the FIFO. The data read from the FIFO has an 8-bit tag and a 16-bit temperature data as shown in <u>Table 8</u>. The controller reads 3N bytes from the FIFO to get N samples.

When the rate change is too fast, a 9-bit temperature slope is saved in the FIFO along with the R[1:0] bits which indicate if the temperature rise or fall is too fast.

FIFO Configuration Registers

There are seven registers (address 0x04 to 0x0A) that control how the FIFO is configured and read out. Details of these registers are given as follows:

FIFO_WR_PTR (address 0x04), Write Pointer

FIFO_WR_PTR[5:0] points to the FIFO location where the next word is written. This pointer advances for each word pushed on to the FIFO by the internal conversion process. The write pointer is updated from a 6-bit counter and wraps around to count 0x00 from count 0x3F.

FIFO_RD_PTR (address 0x05), Read Pointer

FIFO_RD_PTR[5:0] points to the location where the next word of the FIFO is read using the I²C interface. This advances each time a word is read from the FIFO. The read pointer is updated from a 6-bit counter and wraps around to count 0x00 from count 0x3F.

OVF_COUNTER (address 0x06), Overflow Counter

OVF_COUNTER[5:0] logs the number of words lost if new words are written after the FIFO is full. This counter saturates at count value 0x3F. Each time a complete word is popped from the FIFO, the OVF_COUNTER is reset to zero. The counter is useful as a debug tool. It should be read immediately before reading the FIFO in order to check if an overflow condition has occurred.

FIFO_DATA_COUNT (address 0x07), FIFO Data Counter

FIFO_DATA_COUNT[6:0] is a read-only register, which holds the number of words available in the FIFO for the controller to read. This increments when a new word is pushed to the FIFO, and decrements when the controller reads a word from the FIFO.

FIFO_DATA (address 0x08), FIFO Data

FIFO_DATA[7:0] is a read-only register used to retrieve data from the FIFO. It is important to burst read the word from the FIFO. Each word is three bytes. Burst reading three bytes from the FIFO_DATA register advances the FIFO_RD_PTR by one.

FIFO_A_FULL (address 0x09), FIFO Almost Full

The FIFO_A_FULL[5:0] register sets the watermark for the FIFO and determines when the A_FULL[7](0x00) bit in the Status register is asserted. The A_FULL bit is set when the FIFO contains 64 minus FIFO_A_FULL[5:0] words. For example, when FIFO_A_FULL is set to 2, the flag is set when the 62nd word is written to the FIFO. When the FIFO almost full condition is met, the A_FULL bit is asserted in the Status register. If the A_FULL_EN[7](0x02) bit in the Interrupt Enable register is set and INT_OCFG[1:0](0x12) and INT_FCFG[3:2](0x12) are set in the Pin Configuration register, then the interrupt is asserted on the INT pin. This condition should prompt the applications processor to read samples from the FIFO before it fills.

The application processor reads the OVF_COUNTER[5:0](0x06) and FIFO_DATA_COUNT[6:0](0x07) registers, to

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

determine how many data items are in the FIFO.

Alternatively, if the application always responds much faster than the selected sample rate, it could read 64 minus FIFO_A_FULL[5:0] number of data items every time it gets an A_FULL interrupt and be assured that all data from the FIFO are read. This is the preferred way to minimize the traffic on the serial interface. FIFO_WR_PTR, FIFO_RD_PTR, FIFO_DATA_COUNT and OVF_COUNTER registers are available for debug purposes, if needed.

FIFO_RO (address 0x0A), FIFO Rollover

The FIFO_RO[1] bit in the FIFO Configuration 2 register determines whether a sample is pushed onto the FIFO or discarded when it is full. If FIFO_RO is enabled when FIFO is full, old samples are overwritten. If FIFO_RO is not set, the new sample is discarded and the FIFO is not updated.

A_FULL_TYPE (address 0x0A),Almost Full Type

The A_FULL_TYPE[2] bit defines the behavior of the A_FULL status bit. If the A_FULL_TYPE bit is set low, the A_FULL[7](0x00) status bit is asserted when the A_FULL condition is detected and cleared by a STATUS register read, then reasserts for every sample if the A_FULL condition persists. If the A_FULL_TYPE bit is set high, the A_FULL status bit is asserted only when a new A_FULL condition is detected. The status bit is cleared by a STATUS register read and does not reassert for every sample until a new A_FULL condition is detected.

FIFO_STAT_CLR (address 0x0A), FIFO Status Clear

The FIFO_STAT_CLR[3] bit defines whether the A_FULL[7](0x00) and TEMP_RDY[6](0x00) status bits should clear by a FIFO_DATA[7:0](0x08) register read. If FIFO_STAT_CLR is set low, A_FULL and TEMP_RDY status bits are not cleared by a FIFO_DATA register read but are cleared by Status register read. If FIFO_STAT_CLR is set high, A_FULL and TEMP_RDY status bits are cleared by a FIFO_DATA register read or a STATUS register read.

FLUSH_FIFO (address 0x0A)

The FLUSH_FIFO[4] bit is used for flushing the FIFO. The FIFO becomes empty and the FIFO_WR_PTR[5:0](0x04), FIFO_RD_PTR[5:0](0x05), FIFO_DATA_COUNT[6:0](0x07) and OVF_COUNTER[5:0](0x06) are reset to zero. FLUSH_FIFO is a self-clearing bit.

Serial Interface

I²C Target Address

The device responds to its own I²C target address, which is selected using the A0 and A1 pins for the MAX30210. A0 and A1 can be connected to the supply voltage, ground, SDA, or SCL. This provides up to 16 unique addresses for the MAX30210 as shown in <u>Table 9</u>.

A1	A0	ADDR
GND	GND	0x80
GND	V _{DD}	0x82
GND	SCL	0x84

Table 9. I²C Target Address (continued)

I²C/SMBus Compatible Serial Interface

The MAX30210 features an I²C/SMBus-compatible, 2-wire serial interface consisting of an SDA and SCL. The SDA and SCL facilitate communication between the MAX30210 and the controller at clock rates up to 400kHz. Figure 11 shows the 2-wire interface timing diagram. The controller generates SCL and initiates data transfer on the bus. The controller device writes data to the MAX30210 by transmitting the proper target address followed by the register address and then the data word. Each transmit sequence is framed by a START (S) or REPEATED START (Sr) condition and a STOP (P) condition. Each word transmitted to the MAX30210 is 8-bit long and is followed by an acknowledge clock pulse. A controller reading data from the MAX30210 transmits the proper target address followed by a series of nine SCL pulses. The MAX30210 transmits data on SDA in sync with the controller-generated SCL pulses. The controller acknowledges receipt of each byte of data. Each read sequence is framed by a START (S) or REPEATED START (Sr) condition, a not acknowledge, and a STOP (P) condition. The SDA operates as both an input and an open-drain output. A pullup resistor is required on SDA. The SCL operates only as an input. A pullup resistor is required on SCL if there are multiple controllers on the bus, or if the single controller has an open-drain SCL output. Series resistors in line with SDA and SCL are optional. Series resistors protect the digital inputs of the MAX30210 from high voltage spikes on the bus lines and minimize crosstalk and undershoot of the bus signals.

Detailed I²C Timing Diagram

The detailed timing diagram is shown in Figure 11.

Figure 11. Detailed I²C Timing Diagram

Bit Transfer

One data bit is transferred during each SCL cycle. The data on SDA must remain stable during the high period of the SCL pulse. Changes in SDA while SCL is high are control signals (see the <u>START and STOP Conditions</u> section).

START and STOP Conditions

The SDA and SCL idle high when the bus is not in use. A controller initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA while SCL is high (Figure 12). A START condition from the controller signals the beginning of a transmission to the MAX30210. The controller terminates transmission, and frees the bus, by issuing a STOP condition. The bus remains active if a REPEATED START condition is generated instead of a STOP condition.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

Acknowledge Bit

The acknowledge bit (ACK) is a clocked 9th bit that the MAX30210 uses to handshake receipt of each byte of data when in write mode (Figure 13). The MAX30210 pulls down SDA during the entire controller-generated 9th clock pulse if the previous byte is successfully received. Monitoring ACK allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus controller retries communication. The controller pulls down SDA during the 9th clock cycle to acknowledge receipt of data when the MAX30210 is in read mode. An acknowledge is sent by the controller after each read byte to allow data transfer to continue. A not acknowledge is sent when the controller reads the final byte of data from the MAX30210 followed by a STOP condition.

I²C Write Data Format

A write to the MAX30210 includes transmission of a START condition, the target address with the R/W bit set to 0, one byte of data to configure the internal register address pointer, one or more bytes of data, and a STOP condition. Figure 14 illustrates the proper frame format for writing one byte of data to the MAX30210. Figure 15 illustrates the frame format for writing n-bytes of data to the MAX30210.

The controller first sends the target address with the R/W bit set to 0. This indicates that the controller intends to write data to the MAX30210. The MAX30210 acknowledges receipt of the address byte during the controller-generated 9th SCL pulse.

Figure 12. I²C Start (S), Stop (P), and Repeated Start (Sr) Conditions

Figure 13. I²C Acknowledge Bit

The second byte transmitted from the controller configures the MAX30210's internal register address pointer. The pointer tells the MAX30210 where to write the next byte of data. An acknowledge pulse is sent by the MAX30210 upon receipt of the address pointer data.

The third byte sent to the MAX30210 contains the data that is written to the chosen register. An acknowledge pulse from the MAX30210 signals receipt of the data byte. The address pointer auto increments to the next register address after each received data byte. This auto-increment feature allows a controller to write to sequential registers within one continuous frame. The controller signals the end of transmission by issuing a STOP condition. The auto-increment feature is disabled when there is an attempt to write to the FIFO_DATA[7:0] (0x08) register.

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

I²C Read Data Format

The controller sends the target address with the R/\overline{W} bit set to 1 to initiate a read operation. The MAX30210 acknowledges receipt of its target address by pulling SDA low during the 9th SCL clock pulse. A START command followed by a read command resets the address pointer to register 0x00.

Figure 14. I²C Single Byte Write Transaction

Figure 15. I²C Multi-Byte Write Transaction

The first byte transmitted from the MAX30210 contains the data in register 0x00. Transmitted data is valid on the rising edge of SCL. The address pointer auto-increments after each read data byte. This auto-increment feature allows all registers to be read sequentially within one continuous frame. The auto-increment feature is disabled when there is an attempt to read from the FIFO_DATA[7:0](0x08) register, and this allows for burst reading of the FIFO_DATA register. A STOP condition can be issued after any number of read data bytes. If a STOP condition is issued followed by another read operation, the first data byte to be read is from register 0x00. The address pointer can be preset to a specific register before a read command is issued. The controller presets the address pointer by first sending the MAX30210 target address with the R/W bit set to 0 followed by the register address. A REPEATED START condition is then sent followed by the target address with the R/W bit set to 1. The MAX30210 then transmits the contents of the specified

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

register. The address pointer auto-increments after transmitting the first byte.

The controller acknowledges receipt of each read byte during the acknowledge clock pulse. The controller must acknowledge all correctly received bytes except the last byte. The final byte must be followed by a not acknowledge from the controller and then a STOP condition. Figure 16 illustrates the frame format for reading one byte from the MAX30210. Figure 17 illustrates the frame format for reading multiple bytes from the MAX30210.

Access Type	Read Only	y Read Only	Read	Only	Read Only	Read Only	Read Only	_	Read Only
BITFIEI	D	BITS				DE	SCRIPTION		
A_FULL		7		A_FULL is set to 1 when the FIFO has reached the threshold programme the FIFO_A_FULL[5:0](0x09). This is a read-only bit. This bit is cleared w the Status Register is read. It is also cleared when FIFO_DATA[7:0](0x08 register is read. if FIFO_STAT_CLR[3](0x0A) = 1.					
TEMP_RDY		6		TEMP_RDY is asserted when a temperature sensor measurement has completed and new data is available to be read by the controller. This is cleared when the Status Register is read. It is also cleared when FIFO_DATA[7:0](0x08) register is read, if FIFO_STAT_CLR[3](0x0A) =					ent has . This bit is x0A) = 1.
TEMP_DEC_F	EMP_DEC_FAST 5 TEMP_DEC_FAST 5					s too fast. r is read.			

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

BITFIELD	BITS	DESCRIPTION
TEMP_INC_FAST	4	TEMP_INC_FAST is asserted when the temperature increases too fast. This is a read-only bit and it is cleared after the STATUS register is read.
TEMP_LO	3	TEMP_LO is asserted when the latest temperature sensor measurement is less than what is programmed in the Temperature Sensor Alarm Low (0x24,0x25) register. This is a read-only bit and it is cleared after the STATUS register is read. TEMP_LO is not used when ALERT_MODE[7](0x29) is set for Comparator mode.
TEMP_HI	2	TEMP_HI is asserted when the latest temperature sensor measurement is greater than what is programmed in the Temperature Sensor Alarm High (0x22, 0x23) register. This is a read-only bit. When this bit is asserted and if the TEMP_HI_EN bit is set to 1 then it asserts the interrupt on the INT pin. The controller needs to read the status register to determine if the interrupt was asserted by the TEMP_HI status. When ALERT_MODE[7](0x29) is set for Interrupt mode, TEMP_HI and the interrupt are cleared after the STATUS register is read. When ALERT_MODE is set for Comparator mode, TEMP_HI does not clear on STATUS register read, but the interrupt clears on STATUS register read. TEMP_HI remains asserted until the latest temperature sensor measurement goes lower than what is programmed in the Temperature Sensor Alarm Low (0x24, 0x25) register.
PWR_RDY	0	$\begin{array}{l} {\sf PWR_RDY} \text{ is set to 1 when } {\sf V}_{{\sf DD}} \text{ goes below POR threshold, which is} \\ {\sf nominally 1.42V.} \text{ If this condition occurs, all registers are reset to their POR } \\ {\sf state.} \text{ This bit is not triggered by a soft reset.} \text{ This is a read-only bit and it is} \\ {\sf cleared when the Status register is read.} \\ {\sf PWR_RDY} \text{ is a non-maskable interrupt, so it gets asserted on INT pin.} \end{array}$

FIFO Counter 1 (0x06)

BIT	7	6	5	4	3	2	1	0			
Field	-	-		OVF_COUNTER[5:0]							
Reset	-	-		0x00							
Access Type	-	-			Read	Only					

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

BITFIELD	BITS	DESCRIPTION
OVF_COUNTER	5:0	When FIFO is full any new samples will result in new or old samples getting lost depending on FIFO_RO[1](0x0A). OVF_COUNTER counts the number of samples lost. It saturates at 0x3F. This is a read-only register. See the FIFO Description section for details.

FIFO Counter 2 (0x07)

BIT	7	6	5	4	3	2	1	0				
Field	_		FIFO_DATA_COUNT[6:0]									
Reset	_		0x00									
Access Type	_			Read Only								
BITFIE	LD	BITS		DESCRIPTION								
FIFO_DATA_COUNT 6:0 FIFO				FIFO_DATA_COUNT is a read-only register which holds the of the number of items available in the FIFO for the host to read. See the FIFO Description section for details.								

FIFO Data (0x08)

BIT	7	6	5	4	3	2	1	0			
Field		FIFO_DATA[7:0]									
Reset		0x00									
Access Type		Read Only									
BITFIEI	LD	BITS			DE	SCRIPTION					
FIFO_DATA		7:0	FIFC	FIFO_DATA is a read-only register and is used to get data from the I See the FIFO Description section for details.							

FIFO Configuration 1 (0x09)

BIT	7	6	5	4	3	2	1	0		
Field	_	_		FIFO_A_FULL[5:0]						
Reset	_	_		0x1F						
Access Type	-	-			Write,	Read				

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

BITFIELD	BITS		DESCRIPTION				
		FIFO_A_FULL indicates how many new samples can be written to the FIFO before the interrupt is asserted. For example, if set to 0xF, the interrupt triggers when there is 15 empty space left (49 entries), and so on.					
	5:0	FIFO_A_FULL	FREE SPACE BEFORE	NUMBER OF SAMPLES IN FIFO			
		0x0	0	64			
		0x1	1	63			
FIFO A FULL		0x2	2	62

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

BITFIELD	BITS	DESCRIPTION
FIFO_RO	1	FIFO_RO bit controls the behavior of the FIFO when the FIFO becomes completely filled with data. Push to FIFO is enabled when FIFO is full if FIFO_RO = 1 and old samples are lost. Both FIFO_WR_PTR[5:0](0x04) and FIFO_RD_PTR[5:0](0x05) increment for each sample after the FIFO is full. Push to FIFO is disabled when FIFO is full if FIFO_RO = 0 and new samples are lost. FIFO_WR_PTR and FIFO_RD_PTR do not increment for each sample after the FIFO is full. If temperature conversion is in AUTO mode or in External Trigger mode and if CHG_DET_EN[3](0x28) is set to 1, FIFO_RO is ignored and the FIFO always rolls on full. See the FIFO Description section for details.

BITFIELD BITS DESCRIPTION									
AUTO 1 Set AUTO is set to 1 for autonomous mode. In this mode, Whe CONVERT_T is set to 1, the temperature conversions are contrate determined by TEMP_PERIOD[3:0](0x29) register. AUTO 1 When AUTO is set to 0, one temperature conversion is initiated CONVERT_T bit. AUTO bit is ignored if the CVT pin is used for initiating a temperature conversion is initiated for initininitiated for initininitiated					s mode, When ions are contin gister. ion is initiated t ating a tempera on.	uous at the by the ature			

±0.1°C Accurate, Ultra-Small, Low-Power I²C Digital Temperature Sensor

BITFIELD	BITS	DESCRIPTION
CONVERT_T	0	Set CONVERT_T = 1 to start temperature data conversions. This bit stays high while conversion is in progress and is set to zero when the conversion completes. For manual mode with AUTO = 0, the conversion is considered complete after one conversion. For auto mode with AUTO = 1, the conversions are continuous at the sample rate programmed in TEMP_PERIOD[3:0](0x29) register, and will not stop until CONVERT_T bit is deasserted. Set CONVERT_T = 0 to immediately abort any conversion in progress. When writing 0 to CONVERT_T bit, it is important to write 0 to AUTO bit as well. So for auto mode, the conversion is considered complete when AUTO and CONVERT_T bits are set to 0. Writing 1 to the CONVERT_T bit is ignored, if temperature conversion is in progress. CONVERT_T bit is ignored if the CVT pin is used for initiating a temperature conversion. See EXT_CVT_EN[7](0x12) description.
